Functionality

The AD9361 ADC SUB is a subdevice worker whose primary purpose is to de-interleave the AD9361 IC pin-provided time-interleaved RX data streams (independent of which of the IC's P0/P1 buses the RX data stream came from). De-interleaving occurs according to the timing diagrams specified in [2]. This worker ingests RX data from devsignals from ad9361_data_sub.hdl[5], de-interleaves it into at most two 12-bit (Q0.11) RX channel data buses, and makes each channel bus available to an instance of the supported ad9361_adc.hdl device worker via a devsignal port.

Worker Implementation Details

ad9361_adc_sub.hdl

The ad9361_adc_sub.hdl subdevice worker handles registering and de-interleaving of ADC data made available via the dev_data_from_pins devsignal port. This worker's LVDS_p, HALF_DUPLEX_p, SINGLE_PORT_p, and DATA_RATE_CONFIG_p parameter properties allow for and enforce build-time configuration of the possible AD9361 RX data time-interleaved modes. The currently supported modes and their limitations are shown in the following table.

Table 2: Supported ADC Sampling Rates per RX channel

| Platform/Cards which | AD9361 Data Port Mode | AD9361 Channel Mode | Max AD9361- | Max |
|----------------------|----------------------------------|---------------------|---------------------|-------------------------|
| allow the AD9361 | | | Supported Sampling | ad9361_adc_sub.hdl- |
| Data Port/Channel | | | Rate per RX channel | Supported Sampling |
| Mode | | | | Rate per RX channel |
| E310 | CMOS Single Port Half Duplex SDR | | | not yet supported |
| E310 | CMOS Single Port Half Duplex DDR | | | not yet supported |
| E310 | CMOS Single Port Full Duplex SDR | | | not yet supported |
| E310 | CMOS Single Port Full Duplex DDR | | | not yet supported |
| E310 | CMOS Dual Port Half Duplex SDR | | | not yet supported |
| E310 | CMOS Dual Port Half Duplex DDR | | | not yet supported |
| E310 | CMOS Dual Port Full Duplex SDR | | | not yet supported |
| E310 | CMOS Dual Port Full Duplex DDR | | | not yet supported |
| | | 1R1T, 2R2T Timing=0 | 30.72 Msps | 30.72 Msps |
| | | 1R1T, 2R2T Timing=1 | | |
| E310 | CMOS Single Port Full Duplex DDR | 2R1T | 15.36 Msps | 15.36 Msps |
| | | 1R2T | | |
| FMCOMMS2/3 | LVDS (Dual Port Full Duplex DDR) | all configs | 61.44 Msps | 61.44 Msps ¹ |

¹There are limited guarantees of data fidelity on the FMCOMMS2/3 cards for certain multichannel modes on certain platforms, although tests at room temperature have always yielded 100% fidelity. For more info see tables 8 and 9.

Data is sent out the dev_data_ch0_out and dev_data_ch1_out devsignal ports for channel 0 and channel 1, respectively. Note that channel 0 corresponds to the AD9361 R1 channel and channel 1 corresponds to the AD9361 R2 channel when the channels_are_swapped property has a value of false. The channel relationship is otherwise reversed. Note that which of the two AD9361 RX analog RF port's signal is sent in the R1 and R2 time slots are variable depending on the AD9361 register configuration. This relationship is shown in the following table.

ಬ

Table 3: Channel Connectivity (D.C. means Don't Care.)

| channels_are_swapped | ad9361_adc_sub.hdl | | AD9361 RX RF Port | AD9361 | AD9361 | AD9361 |

| Truc | | 102 | 10.12011 / 10.12011 | | [[1 D.O.] | 110000 |

 $^{^2}$ Note that AD9361 register 0x010 Bit D4 is controlled by no-OS's AD9361_InitParam struct's rx_channel_swap_enable member[2] and that the ad9361_config_proxy.rcc worker's ad9361_init property sets that member value[6].

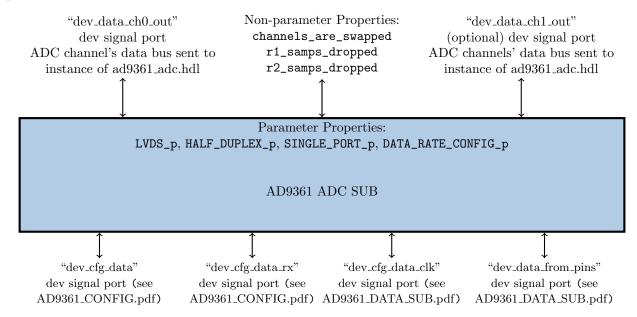

³Note that AD9361 register 0x003 Bits [D7 D6] are controlled by no-OS's AD9361_InitParam struct's one_rx_one_tx_use_rx_num member and two_rx_two_tx_mode_enable member[2] and that the ad9361_config_proxy.rcc worker's ad9361_init property sets these member values[6].

⁴Note that data will only ever be de-interleaved for the R2 time slot and sent out the devisignal when the AD9361 register 0x010 bit D2 is 1 (which forces 2R2T timing) or when AD9361 register 0x003 Bits D7 and D6 are 1 (which corresponds to one of 2R1T or 2R2T mode)

Component Spec Properties

| Name | Type | SequenceLength | ArrayDimensions | Accessibility | Valid Range | Default | Usage |
|------|------|----------------|-----------------|---------------|-------------|---------|-------|
| - | - | - | - | - | - | - | - |

Worker Properties

$ad9361_adc_sub.hdl$

| Scope | Name | Type | SequenceLength | ArrayDimensions | Accessibility | Valid Range | Default | Usage |
|----------|----------------------|------|----------------|-----------------|-----------------------|-------------|---------|---|
| Property | LVDS_p | Bool | - | - | Parameter | Standard | False | Use LVDS RX data bus de-interleaving scheme, otherwise use CMOS de-interleaving scheme. Default is CMOS. |
| Property | HALF_DUPLEX_p | Bool | - | - | Parameter | Standard | False | Use half duplex mode, otherwise use full duplex mode. Must be false when using LVDS mode. |
| Property | SINGLE_PORT_p | Bool | - | - | Parameter | Standard | False | Use single port, otherwise use both (dual) ports. Default is to use both ports. Must be false when using LVDS mode. |
| Property | DATA_RATE_CONFIG_p | Enum | - | - | Parameter | SDR, DDR | DDR | This should have a value of DDR when LVDS_p has a value of true. Either value is acceptable when LVDS_p has a value of false (i.e. CMOS mode is used). |
| Property | channels_are_swapped | Bool | - | - | Readable, Writable | Standard | False | This property exists not as a necessity driven from AD9361 functionality which must be accounted for, but rather as a convenient option to allow control of the routing between the AD9361 pin interface channels (R1 or R2 in the timing diagrams) and this worker's devsignal channels (0 or 1). When this property has a value of true, R1 is routed to channel 0 and R2 to channel 1. When false, the channel relationships are swapped. |
| Property | r1_samps_dropped | Bool | - | - | Volatile, Writable | Standard | - | A value of true indicates that one or more samples were sent from AD9361 for its R1 channel (see UG-570 timing diagrams) at a moment in time where no ad9361_adc.hdl worker was assigned to ingest them. A value of true is only possible when an assembly is built with only one ad9361_adc.hdl worker and when this worker's channels_are_swapped property has a value of true, together which is an erroneous condition which should be avoided. The purpose of this property is to be an error check for the aforementioned erroneous condition. Writing a value of false will force the value to false. Writing a value of true will do nothing. |
| Property | r2_samps_dropped | Bool | - | - | Volatile, Writable | Standard | - | A value of true indicates that one or more samples were sent from AD9361 for its R2 channel (see UG-570 timing diagrams) at a moment in time where no ad9361_adc.hdl worker was assigned to ingest them. A value of true is possible, for example, when when an assembly is built with only one ad9361_adc.hdl worker and the AD9361 is configured for multichannel mode (2X2), together which is an erroneous condition which should be avoided. The purpose of this property is to be an error check for the aforementioned erroneous condition. Writing a value of false will force the value to false. Writing a value of true will do nothing. |

Component Ports

| Name | Producer | Protocol | Optional | Advanced | Usage |
|------|----------|----------|----------|----------|-------|
| - | - | - | - | - | - |

Worker Interfaces

$ad9361_adc_sub.hdl$

| Туре | Name | Count | Optional | Master | Signal | Direction | Width | Description |
|-----------|--------------------------------|-------|----------|--------|--------------------------|-----------|--|--|
| | | | | | config_is_two_r | Input | 1 | If 0, de-interleaving of R2 time slot data and monitoring of data drops via the r2_samps_dropped property are both disabled. |
| | | | | | ch0_handler_is_present | Output | 1 | Value is 1 if the dev_data_ch0 dev signal is connected to a worker (that "handles" the data) and 0 otherwise. This is expected to be hardcoded at buildtime. |
| | | | | | ch1_handler_is_present | Output | 1 | Value is 1 if the dev_data_ch1 dev signal is connected to a worker (that "handles" the data) and 0 otherwise. This is expected to be hardcoded at buildtime. |
| | | | | | data_bus_index_direction | Output | 1 | Value is 1 if the bus indexing of the P0_D/P1_D signals from dev_data_from_pins was reversed before processing. This is expected to be hardcoded at buildtime. |
| | | | | | data_clk_is_inverted | Output | 1 | Value is 1 if the clock in via dev_data_clk was inverted inside this worker before used as an active-edge rising clock. This is expected to be hardcoded at buildtime. |
| | DevSignal dev_cfg_data 1 False | | | islvds | Output | 1 | Value is 1 if LVDS_p has a value of true and 0 if LVDS_p has a value of false. Because LVDS_p is a parameter property, this is hardcoded at buildtime. The purpose of this devsignal is to feed this worker's buildtime-specified LVDS/CMOS mode through ad9361_config_hdl to ad9361_config_proxy.rcc so No-OS knows which LVDS/C-MOS mode to use when initializing the AD9361 IC. | |
| DevSignal | | 1 | 1 False | True | isdualport | Output | 1 | Value is 1 if SINGLE_PORT_p has a value of false and 0 if SINGLE_PORT_p has a value of true. Because SINGLE_PORT_p is a parameter property, this is hardcoded at buildtime. The purpose of this devsignal is to feed this worker's buildtime-specified single/dual port mode through ad9361_config.hdl to ad9361_config_proxy.rcc so No-OS knows which single/dual port mode to use when initializing the AD9361 IC. |
| | | | | | isfullduplex | Output | 1 | Value is 1 if HALF_DUPLEX_p has a value of false and 0 if HALF_DUPLEX_p has a value of true. Because HALF_DUPLEX_p is a parameter property, this is hardcoded at buildtime. The purpose of this devsignal is to feed this worker's buildtime-specified half/full duplex mode through ad9361_config.hdl to ad9361_config_proxy.rcc so No-OS knows which half/full duplex mode to use when initializing the AD9361 IC. |
| | | | | | isDDR | Output | 1 | Value is 1 if DATA_RATE_CONFIG_p has a value of DDR and 0 if DATA_RATE_CONFIG_p has a value of SDR. Because DATA_RATE_CONFIG_p is a parameter property, this is hard-coded at buildtime. The purpose of this devsignal is to feed this worker's buildtime-specified SDR/DDR mode through ad9361.config.hdl to ad9361.config_proxy.rcc so No-OS knows which half/full duplex mode to use when initializing the AD9361 IC. |
| | | | | | present | Output | 1 | Used to communicate to ad9361_config.hdl that it should validate the islvds, isdualport, isfullduplex, and isddr signals against similar signals in the ad9361_dac_sub.hdl and ad9361_data_sub.hdl workers if they are present in the bitstream. This is expected to be hardcoded at buildtime. |

| | | | | | rx_frame_usage | Output | 1 | Value is 1 if worker was built with the assumption that the RX frame operates in its toggle setting and 0 if the |
|-----------|--------------------|---|-------|-------|--------------------------|--------|----|--|
| DevSignal | dev_cfg_data_rx | 1 | False | True | | | | assumption was that RX frame has a rising edge on the first sample and then stays high. This value is intended to match that of AD9361 register 0x010 BIT D3[3]. This is expected to be hardcoded at buildtime. |
| | | | | | rx_frame_is_inverted | Output | 1 | RX path-specific data port configuration. Used to tell |
| | | | | | 1X_II allie_is_liiverted | Output | 1 | other workers about the configuration that was enforced |
| | | | | | | | | when this worker was compiled. This is expected to be |
| | | | | | | | | hardcoded at buildtime. |
| DevSignal | dev_data_clk | 1 | False | True | DATA_CLK_P | Input | 1 | Buffered version of AD9361 DATA_CLK_P pin. |
| | | | | | | 1 1 | | Data bus containing configuration-specific AD9361 pins |
| DevSignal | dev_data_from_pins | 1 | False | True | data | Input | 24 | corresponding to the RX data path: * CMOS single port half duplex: [12'b0 P0_D[11:0]], * CMOS single port full duplex: [18'b0 P0_D[5:0]], * CMOS dual port half duplex: [P0_D[11:0] P1_D[11:0]], * CMOS dual port full duplex: [12'b0 P0_D[11:0]], * LVDS: [18'b0 RX_D[5:0]], or, if ports are swapped: * CMOS single port half duplex: [12'b0 P1_D[11:0]], * CMOS single port full duplex: [18'b0 P1_D[5:0]], * CMOS dual port half duplex: [P1_D[11:0] P0_D[11:0]], * CMOS dual port full duplex: [12'b0 P1_D[11:0]], * LVDS: (unsupported with port swap). For more info see [5]. |
| | | | | | rx_frame | Input | 1 | Output of buffer whose input is the AD9361 RX_FRAME_P pin's signal. |
| | | | | | present | Output | 1 | Value is 1 if a worker is connected to this devisignal port. |
| | | | | | adc_data_I | Input | 12 | Signed Q0.11 I value of ADC sample corresponding to RX channel 0. |
| DevSignal | dev_data_ch0_out | 1 | False | False | adc_data_Q | Input | 12 | Signed Q0.11 Q value of ADC sample corresponding to RX channel 0. |
| | | | | | adc_clk | Input | 1 | Clock for adc_data_I, adc_data_Q, and adc_give. |
| | | | | | adc_give | Input | 1 | Indicates that the adc_data_I and adc_data_Q are valid and |
| | | | | | | | | should be latched on the next rising edge of adc_clk. |
| | | | | | present | Output | 1 | Value is 1 if a worker is connected to this devsignal port. |
| | | | | | adc_data_I | Input | 12 | Signed Q0.11 I value of ADC sample corresponding to RX channel 1. |
| DevSignal | dev_data_ch1_out | 1 | True | False | adc_data_Q | Input | 12 | Signed Q0.11 Q value of ADC sample corresponding to RX channel 1. |
| | | | | | adc_clk | Input | 1 | Clock for adc_data_I, adc_data_Q, and adc_give. |
| | | | | | adc_give | Input | 1 | Indicates that the adc_data_I and adc_data_Q are valid and should be latched on the next rising edge of adc_clk. |

Subdevice Connections

| Supports Worker | Supports Worker Port | ad9361_adc_sub.hdl Port | ad9361_adc_sub.hdl Port Index |
|-----------------|----------------------|-------------------------|-------------------------------|
| ad9361_adc | dev_adc | dev_data_ch0_out | 0 |
| ad9361_adc | dev_adc | dev_data_ch1_out | 0 |

Control Timing and Signals

Clock Domains

The AD9361 ADC SUB subdevice worker contains two clock domains: the clock from the Control Plane, and the AD9361 DATA_CLK_P clock from the dev_data_clk devsignal. The control clock domain is only used to read or write the channels_are_swapped, r1_samps_dropped, and r2_samps_dropped properties (all of which are synchronized between the clock domains in one direction or the other). The DATA_CLK_P domain is used for the registering/de-interleaving of RX data. The data sent out the dev_data_ch0_out and dev_data_ch1_out dev signals is on the DATA_CLK_P domain.

Latency

For the LVDS configuration or CMOS Single Port Full Duplex (DDR) configuration, the latency from the first active edge of the AD9361 DATA_CLK_P clock on which an R1 channel's sample begins to the first rising edge of the output clock on the dev_data_ch0_out/dev_data_ch1_out port for the same sample is 6 DATA_CLK_P cycles. For these modes, the latency from the first active edge of the AD9361 DATA_CLK_P clock on which an R2 channel's sample begins to the first rising edge of the output clock on the dev_data_ch0_out/dev_data_ch1_out port for the same sample is 4 DATA_CLK_P cycles.

Multichannel Phase Coherency

Note that the aforementioned 6 cycle/4 cycle latency results on the multichannel data being output the devsignal ports in a clock-aligned, phase coherent fashion. However, just because the each channel's devsignal data is phase-aligned at the output of the ad9361_adc_sub.hdl worker's devsignals, that does not mean that the data is phase-aligned once each channel is ingested inside an instance of an ad9361_adc.hdl device worker because each ad9361_adc.hdl instance handles its data as an independent, uniquely flow-controlled data path.

Worker Configuration Parameters

$ad9361_adc_sub.hdl$

Table 5: Table of Worker Configurations for worker: ad9361_adc_sub

| Configuration | DATA_RATE_CONFIG_p | HALF_DUPLEX_p | SINGLE_PORT_p | LVDS_p |
|---------------|--------------------|---------------|---------------|--------|
| 0 | DDR | false | false | true |
| 1 | DDR | false | true | false |

Performance and Resource Utilization

$ad9361_adc_sub.hdl$

The FPGA resource utilization and Fmax are included for this worker. Fmax refers to the maximum allowable clock rate for any registered signal paths within a given clock domain for an FPGA design. Fmax in the table below is specific only to this worker and represents the maximum possible Fmax for any OpenCPI bitstream built with this worker included. Note that the Fmax value for a given clock domain for the final bitstream is often worse than the Fmax specific to this worker, even if this worker is the only one included in the bitstream. It's important to note that the full range of possible operating conditions for the AD9361 is not guaranteed to operate without error, e.g. maximum achievable RX sample rates in certain LVDS modes are less than AD9361 LVDS mode-maximum of 245.76 MHz[2]. For more information, see Tables 7, 8, and 9.

In the tables below, dev_data_clk is the worker source code name for the signal which is ultimately driven by, and has the same clock rate of, the AD9361 DATA_CLK pin pair.

Table 6: Resource Utilization Table for worker: ad9361_adc

| Configuration | OCPI Target | Tool | Version | Device | Registers | LUTs | Fmax (N | MHz) (Typ) | Memory/Special |
|---------------|-------------|--------|---------|------------------|-----------|-------|-------------------------------|------------|----------------|
| | | | | | (Typ) | (Typ) | | | Functions |
| | | | | | | | control plane dev_adc.adc_clk | | |

 $^{^{1}}$ These measurements were the result of a Vivado timing analysis which was different from the Vivado analysis performed by default for OpenCPI worker builds. For more info see Appendix 1

A notable example of the aforementioned potential discrepancy between worker Fmax and bitstream Fmax for a given clock domain is the maximum achievable AD9361 LVDS RX data clock rate for Zynq 7020 speed grade 1 bitstreams containing this worker. The bitstream Fmax in this case is significantly lower than the worker netlist Fmax of 418MHz on a Zynq 7020 speed grade 1. The timing analysis for the ad9361_adc_sub netlist is not capable of taking into account the paths from the internal-to-the-AD9361 registers which produce the RX data to the ad9361_adc_sub worker's DDR register inputs. The Fmax discrepancy in this case results from these external-to-the-ad9361_adc_sub paths being the limiting factor for the max bistream RX data clock rate. In order to perform a timing analysis which does include these paths, and therefore takes into account all paths which may limit the maximum achievable RX data clock rate, a timing analysis must be done 1) on a netlist/bitstream which includes the rest of the path from the DDR input from the FPGA pad (i.e. it includes the ad9361_data_sub worker) and 2) which includes delay/offset constraints which contain the information about the range of possible clock/data skews from the internal-to-the-AD9361 register which produced the RX data to the FPGA pad (i.e. constraints are used which include the AD9361 datasheet-specified t_{DDRX} and t_{DDDV} min/max values).

Table 7 includes the known theoretical limitations at the bitstream level (as opposed to ad9361_adc_sub level) for the AD9361 DATA_CLK clock rate for various hardware/software configurations. For convenience, Table 8 converts the AD9361 DATA_CLK rate limitations into their consequential RX sample rate limitations. Table 9 contains the experimental verification results for RX sample rate limitations.

Table 7: Theoretical bitstream clock period limitations for dev_data_clk (AD9361 DATA_CLK) clock domain.

| Parameter | Conditions | Min | Typ | Max | Unit | Notes |
|---|---|---|-----------|--------------------|------|--|
| min dev_data_clk (AD9361 DATA_CLK) clock period | | Min 5.712 ¹ 4.294 ¹ | Typ 3.545 | 5.712 ¹ | ns | (approx 175.070028011 MHz), guaranteed by FPGA timing analysis (approx 232.883092687 MHz), guaranteed by FPGA timing analysis (approx 282 MHz), guaranteed by FPGA timing analysis |
| | AD9361 Single Data Rate=0 AD9361 DATA_CLK Delay=11, AD9361 Rx Data Delay=0 | 16.276 | | 16.276 | ns | (approx 61.44 MHz), guaranteed by FPGA timing analysis |

¹Note this is more than the minimum AD9361 LVDS DATA_CLK Clock Period of 4.069 ns, i.e. not all possible AD9361 LVDS clock rates can be accounted for.

²Note that a) this condition is driven by the limitations of the capabilities of Xilinx ISE/Vivado constraints, and b) the range of value(s) for this condition does not cover the full range of possible values for AD9361 for the given mode.

1 Appendix - Vivado Timing Analysis

The Vivado timing report that OpenCPI runs for device workers may erroneously report a max delay for a clocking path which should have been ignored. Custom Vivado tcl commands had to be run for this device worker to extract pertinent information from Vivado timing analysis. After building the worker, the following commands were run from the assets project directory (after the Vivado settings64.sh was sourced):

```
cd hdl/devices/
vivado -mode tcl
```

Then the following commands were run inside the Vivado tcl terminal. Note this example is for build configuration 0 only.

```
open_project ad9361_adc_sub.hdl/target-zynq/ad9361_adc_sub_rv.xpr
synth_design -part xc7z020clg484-1 -top ad9361_adc_sub_rv -mode out_of_context
create_clock -name clk1 -period 0.001 [get_nets {ctl_in[Clk]}]
create_clock -name clk2 -period 0.001 [get_nets {dev_data_clk_in[DATA_CLK_P]}]
set_clock_groups -asynchronous -group [get_clocks clk1] -group [get_clocks clk2]
report_timing -delay_type min_max -sort_by slack -input_pins -group clk1
report_timing -delay_type min_max -sort_by slack -input_pins -group clk2
```

The following is the output of the timing reports. The Fmax for the control plane clock for this worker is computed as the maximum magnitude slack with a control plane clock of 1 ps plus 2 times the assumed 1 ps control plane clock period (3.172 ns + 0.002 ns = 3.174 ns, 1/3.174 ns = 315.06 MHz). The Fmax for the dev_data_clk clock from the devsignal is computed as the maximum magnitude slack with dev_data_clk of 1 ps plus 2 times the assumed 1 ps dev_data_clk period (2.387 ns + 0.002 ns = 2.389 ns, 1/2.389 ns = 418.59 MHz).

                  FDRE (Setup_fdre_C_CE) -0.202 1.713 worker/data_mode_lvds.adc_r1_i_h_rrr_reg[0]
                                                 1.713
                  required time
                  arrival time
                                                 -4.100
```

These calculations can be verified by replacing the create_clock lines above with the following values and rerunning the report_timing commands and observing a value of 0.000 ns for the slacks:

```
create_clock -name clk1 -period 3.174 [get_nets {ctl_in[Clk]}]
create_clock -name clk2 -period 2.389 [get_nets {dev_data_clk_in[DATA_CLK_P]}]
report_timing -delay_type min_max -sort_by slack -input_pins -group clk1
report_timing -delay_type min_max -sort_by slack -input_pins -group clk2
```

For the clk2 example:

```
Vivado% report_timing -delay_type min_max -sort_by slack -input_pins -group clk2
